

05 - More Files, Chaining Commands, Piping and Redirection

CS 2043: Unix Tools and Scripting, Spring 2017 [1]

Stephen McDowell

February 3rd, 2017

Cornell University

Table of contents

1. Recap on Permissions
2. File Compression
3. Assorted Commands
4. Chaining Commands

Some Logistics

- OH have changed, refer to the syllabus page
- WHY IS MY VM RUNNING SO SLOW?!
 - If you started following step 5 on Getting Started...
 - ...you have to do **BOTH** steps!
 - Reminder: tailor the configurations to be your own.
- Assignments and release dates.

Recap on Permissions

The Octal Version of `chmod`

- Previously, I linked you to [2] for a good explanation.
- For the formula hungry, you can represent `r`, `w`, and `x` as binary variables (where 0 is off, and 1 is on). Then the formula for the modes is

$$r \cdot 2^2 + w \cdot 2^1 + x \cdot 2^0$$

Examples

```
chmod 755: rwxr-xr-x
```

```
chmod 777: rwxrwxrwx
```

```
chmod 600: rw-----
```

- If that makes less sense to you, feel free to ignore it.

Super Confused...

- Elevate your workflow:

Superuser Do

```
sudo <command>
```

- Execute **<command>** as the super user.
 - The regular user (e.g. **student**) is executing the **sudo** command, *not* the **root**.
 - You enter *your* user password.
 - You can only execute **sudo** if you are an "administrator"*.
- On the course VMs the **student** user originally had the password **student**, so that is what you would type if you were executing **sudo**.
 - On your personal Mac (or native Linux install), you would be typing whatever your password is to login to the computer.

Super Confused...

- If you know the **root** password, then you can become **root** using **su** directly.

Switch User

```
su <user_name>
```

- Switches to user **user_name**.
 - The password you enter is the password for **user_name**.
 - If no username is specified, **root** is implied.
- The commands **sudo su root** and **sudo su** are equivalent:
 - Since you typed **sudo** first, that is why you type the user password.
 - If you just execute **su** directly, then you have to type the **root** password.

Default Permissions

- When you create files during a particular session, the mode you are running in determines what the permissions will be.

User mask

`umask <mode>`

- Remove **mode** from the file's permissions.
- Similar syntax to **chmod**:
 - `umask 077`: full access to the user, no access to anybody else.
 - `umask g+w`: enables group write permissions.
 - `umask -S`: display the current mask.
- Changing the **umask** only applies for the remainder of the session (e.g. until you close the terminal window you were writing this in).
- If this has meaning, it is just a bit mask with **0o777**.

File Compression

Making Archives: Zip

Zip

```
zip <name_of_archive> <files_to_include>
```

- Note I said *files*.
 - E.g. `zip files.zip a.txt b.txt c.txt`
 - These will extract to `a.txt`, `b.txt`, and `c.txt` in the current directory.
- To do folders, you need recursion.
 - `zip -r folder.zip my_files/`
 - This will extract to a folder named `my_files`, with whatever was inside of it in tact.

Unzip

```
unzip <archive_name>
```

Note: The original files DO stay in tact.

Making Archives: Gzip

Gzip

```
gzip <files_to_compress>
```

- Less time to compress, larger file: `--fast`
- More time to compress, smaller file: `--best`
- Read the `man` page, lots of options.

Gunzip

```
gunzip <archive_name>
```

Notes:

- By default, *replaces* the original files!
 - You can use `--keep` to bypass this.
- Does not bundle the files.
- Usually has better compression than `zip`.

Making Archives: Tar

- Bundling files together to compress is easy!

Tape Archive

```
tar -cf <tar_archive_name> <files_to_compress>
```

- Create a tar archive.

```
tar -xf <tar_archive_name>
```

- Extract all files from archive.

- Notes:
- **tar** is just a bundling suite, creating a single file.
- By default, it does *not* compress.
- Original files DO stay in tact.
- Unlike **zip**, you do not need the **-r** flag for folders :)

Making Archives: Tarballs

- Combine `tar` and a compression utility to make a *tarball*.

Making tarballs

```
tar -c(z/j)f <archive_name> <source_files>
tar -x(z/j)f <archive_name>
```

- (z/j) here means *either* z or j, **not** both.
- The `-z` flag specifies **gzip** as the compression method.
- YOU have to specify the file extension.
 - Extension convention: **.tar.gz**
 - Example: `tar -cjf files.tar.gz files/`
- The `-j` flag specifies **bzip2** as the compression method.
 - Extension convention: **.tar.bz2**
 - Example: `tar -cjf files.tar.bz2 files/`

Pro Tip: Minimize your Keystrokes

- Extraction can *usually* happen automatically:
 - `tar -xf files.tar.gz` will usually work (no `-z`)
- It's the flag equivalent of the **tab** key.
 - Ok, maybe not...but just remember it!
 - This serves as a not-so-subtle reminder to obsessively hit your **tab** key ;)

Assorted Commands

Before we can Chain...

...we need some more interesting tools to chain together!

Counting

- Ever wanted to show off how cool you are?

Word Count

```
wc [options] <file>
```

- l: count the number of lines.
- w: count the number of words.
- m: count the number of characters.
- c: count the number of bytes.

- Great for things like:
 - Reveling in the number of lines you have programmed.
 - Analyzing the verbosity of your personal statement.
 - Showing people how cool you are.
 - Completing homework assignments?

Sorting

- You don't even need to use your brain to sort things anymore!

Sort

```
sort [options] <file>
```

- Default: sort by the **ASCII** code (roughly alphabetical) for the whole line.
- Use **-r** to reverse the order.
- Use **-n** to sort by numerical order.
- Use **-u** to remove duplicates.

```
$ cat peeps.txt  
Manson, Charles  
Bundy, Ted  
Bundy, Jed  
Nevs, Sven  
Nevs, Sven
```

```
$ sort -r peeps.txt  
Nevs, Sven  
Nevs, Sven  
Manson, Charles  
Bundy, Ted  
Bundy, Jed
```

```
$ sort -ru peeps.txt  
Nevs, Sven  
Manson, Charles  
Bundy, Ted  
Bundy, Jed  
# only 1 Nevs, Sven
```

Advanced Sorting

- The `sort` command is quite powerful, for example you can do:

```
$ sort -n -k 2 -t "," <filename>
```

- Sorts the file numerically by using the second column, separating by a comma as the delimiter instead of a space.
- Read the `man` page!

```
$ cat numbers.txt  
02,there  
04,how  
01,hi  
06,you  
03,bob  
05,are
```

```
$ sort -n -k 2 -t "," numbers.txt  
01,hi  
02,there  
03,bob  
04,how  
05,are  
06,you
```

Unique

```
uniq [options] <file>
```

- No flags: discards all but one of successive identical lines.
- Use `-c` to prints the number of successive identical lines next to each line.

Search and Replace

- Translate characters and sets (but not regular expressions) easily!

Translate

```
tr [options] <set1> [set2]
```

- Translate or delete characters.
 - Sets are strings of characters.
 - By default, searches for strings matching **set1** and replaces them with **set2**.
 - You can use POSIX and custom-defined *sets* (we'll get there soon!).
- The **tr** command only works with streams.
 - Examples to come after we learn about chaining commands in the next section.

Chaining Commands

Your Environment and Variables

- There are various environment variables defined in your environment. They are almost always all capital letters.
- You obtain their value by dereferencing them with a \$.

```
$ echo $PWD      # present working directory
$ echo $OLDPWD   # print previous working directory
$ printenv       # print all environment variables
```

- When you execute commands, they have something called an "exit code".
- The exit code of the last command executed is stored in the \$? environment variable.

What is Defined?

- The environment:
 - `env`: displays all environment variables.
 - `unsetenv <name>`: remove an environment variable.
- The local variables:
 - `set`: displays all shell / local variables.
 - `unset <name>`: remove a shell variable.
- We'll cover these a little more when we talk about customizing your terminal shell.

Exit Codes

- There are various exit codes, here are a few examples:

```
$ super_awesome_command
bash: super_awesome_command: command not found...
$ echo $?
127
$ echo "What is the exit code we want?"
$ echo $?
0
```

- The success code we want is actually **0**. Refer to [3] for some more examples.
- Remember that `cat /dev/urandom` trickery? You will have to `ctrl+c` to kill it, what would the exit code be?

Executing Multiple Commands in a Row

- With exit codes, we can define some simple rules to chain commands together:
 - Always execute:

```
$ cmd1; cmd2 # exec cmd1 first, then cmd2
```

- Execute conditioned upon exit code:

```
$ cmd1 && cmd2 # exec cmd2 only if cmd1 returned 0  
$ cmd1 || cmd2 # exec cmd2 only if cmd1 returned NOT 0
```

- Kind of backwards, in terms of what means continue for *and*, but that was likely easier to implement since there is only one 0 and many not 0's.

Piping Commands

- Bash scripting is all about combining simple commands together to do more powerful things. This is accomplished using the "pipe" character.

Piping

```
<command1> | <command2>
```

- Passes the output from **command1** to be the input of **command2**.
- Works for *heaps* of programs that take input and provide output to the terminal.

Some Piping Examples

Piping along...

```
$ ls -al /bin | less
```

- Allows you to scroll through the long list of programs in `/bin`

```
$ history | tail -20 | head -10
```

- Displays the 10th - 19th previous commands from the previous session.

```
$ echo * | tr ' ' '\n'
```

- Replaces all spaces characters with new lines.
- Execute just `echo *` to see the difference.

Redirection

- To redirect input / output streams, you can use one of `>`, `>>`, `<`, or `<<`.
 - To redirect standard output, use the `>` operator.
 - `command > file`
 - To redirect standard input, use the `<` operator.
 - `command < file`
 - To redirect standard error, use the `>` operator and specify the stream number `2`.
 - `command 2> file`
 - Combine streams together by using `2>&1` syntax.
 - This says: send standard error to where standard output is going.
 - Useful for debugging / catching error messages...
 - ...or ignoring them (you will often see that sent to `/dev/null`).

Redirection Example

- Bash processes I/O redirection from left to right, allowing us to do fun things like this:

Magic

```
tr -cd '0-9' < test1.txt > test2.txt
```

- Deletes everything but the numbers from `test1.txt`, then store them in `test2.txt`.
 - CAUTION: do not *ever* use the same file as output that was input.
 - Example: `tr -cd '0-9' < original.txt > original.txt`
 - You will *lose* all your data, you cannot read and write this way.
- Piping and Redirection are quite sophisticated, please refer to the Wikipedia page in [4].
